

Triton Beam Development

Ashton Morelock

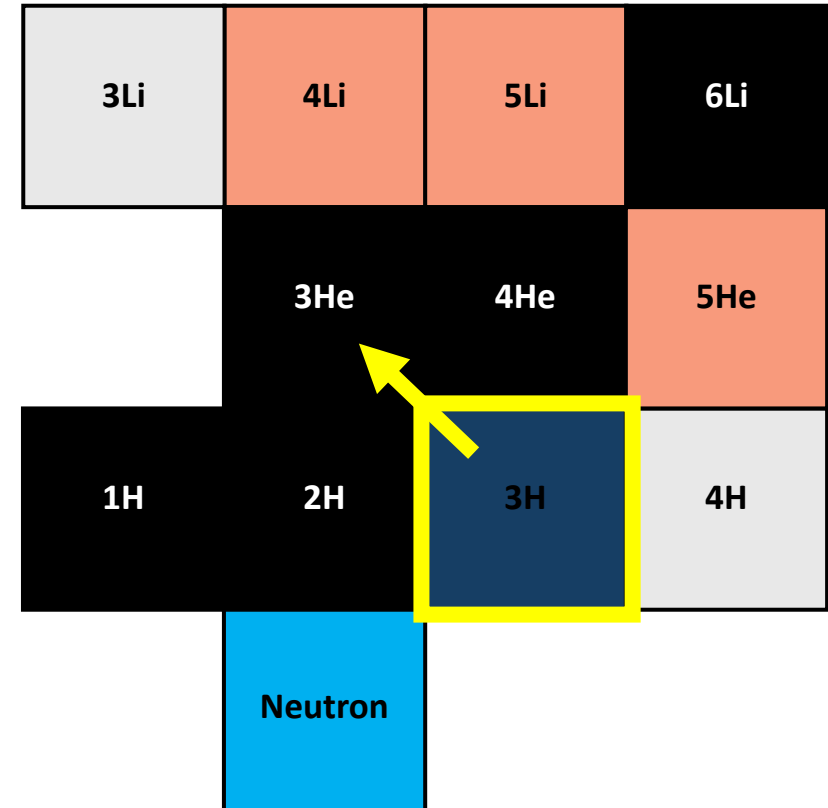

Tritium Background

- No facility currently exists in the U.S. to produce pure, low energy (3-17 MeV) tritium beams.
 - (t,p) , (t,n) , (t,α) , $(t, {}^3\text{He})$, $t+t$
- There are a significant number of nuclear reactions involving tritium that are crucial for Stockpile Stewardship, Nuclear Fusion, Nuclear Structure, and Nuclear Astrophysics. For many of these, the cross-sections and the distribution of reaction products are either unknown or uncertain.
- Tritium was successfully and safely run in the past (UPenn and McMaster) using sputter (solid state) sources.
 - Tritium contamination was not a problem.

Tritium Background

- $t_{1/2} = 12.32$ years
- ${}^3\text{H} \rightarrow {}^3\text{He} + e^- + \bar{\nu}_e$; $Q(\beta^-) = 18.6$ keV
 - Travels less than 7 mm in air
 - Cannot penetrate dead layer of skin
 - Cannot penetrate clothing or gloves
- Internal exposure
 - Inhalation
 - Absorption
 - Ingestion

Triton Beam Project at FSU

- FSU-UTK-ORNL collaboration to install a dedicated MC-SNICS for triton beams at the John D. Fox laboratory, backed by NNSA and CENTAUR
 - **Safely** explore questions for Stockpile Stewardship, Nuclear Structure, etc. using tritium
- Paired with the new Super-Enge Split Pole Spectrograph (SE-SPS), safely produce and handle triton beams from 3 – 17 MeV for nuclear physics experiments

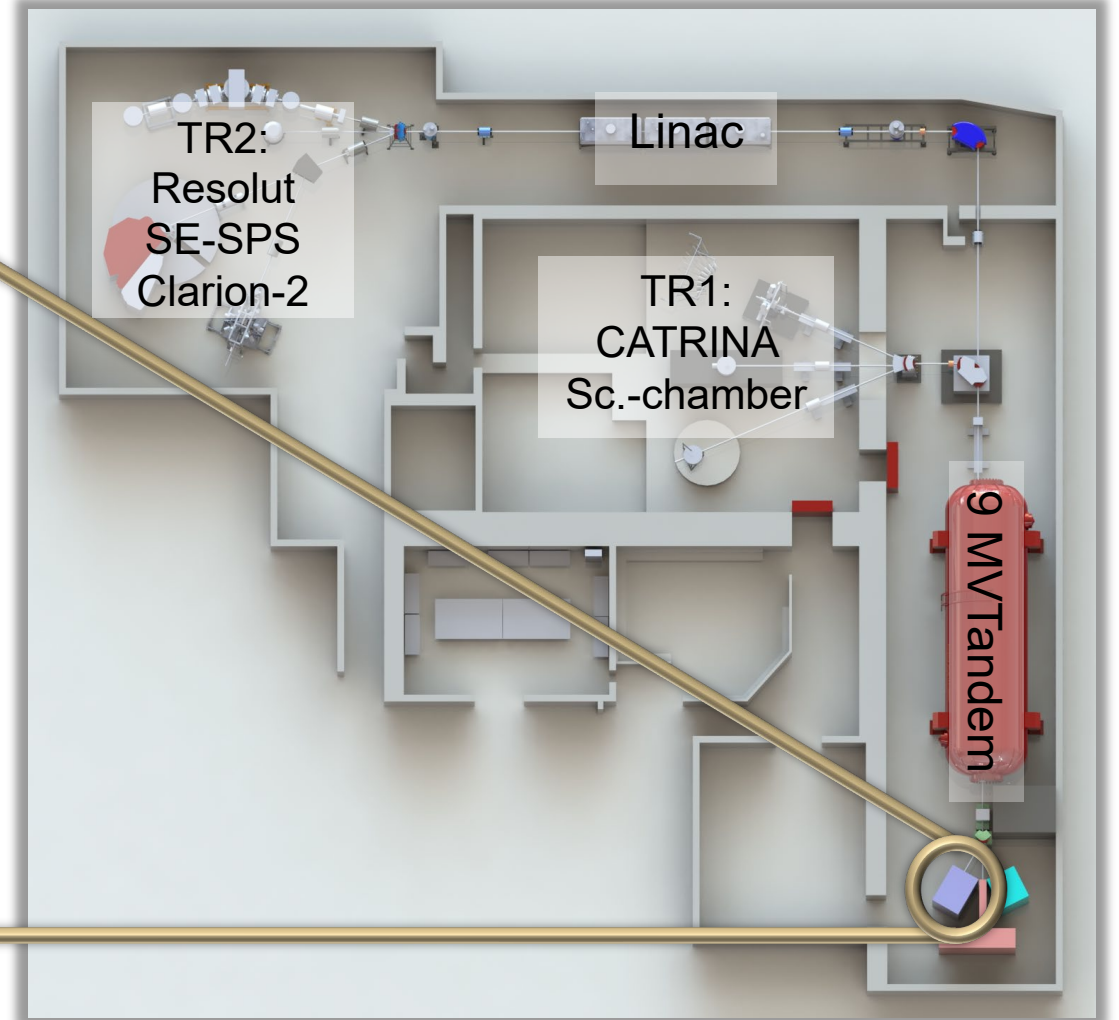

University of Pennsylvania Tritium Source

- Pioneered hydrogen beams from solid-state material
- Titanium Sublimation Pumps
- Beam current: $0.25 \mu\text{A} - 4 \mu\text{A}$
- Transmission : $\sim 75\% - 33\%$
- Report negligible contamination of the accelerator
 - Report $5\mu\text{C}/\text{cm}^2$ in inflector magnet

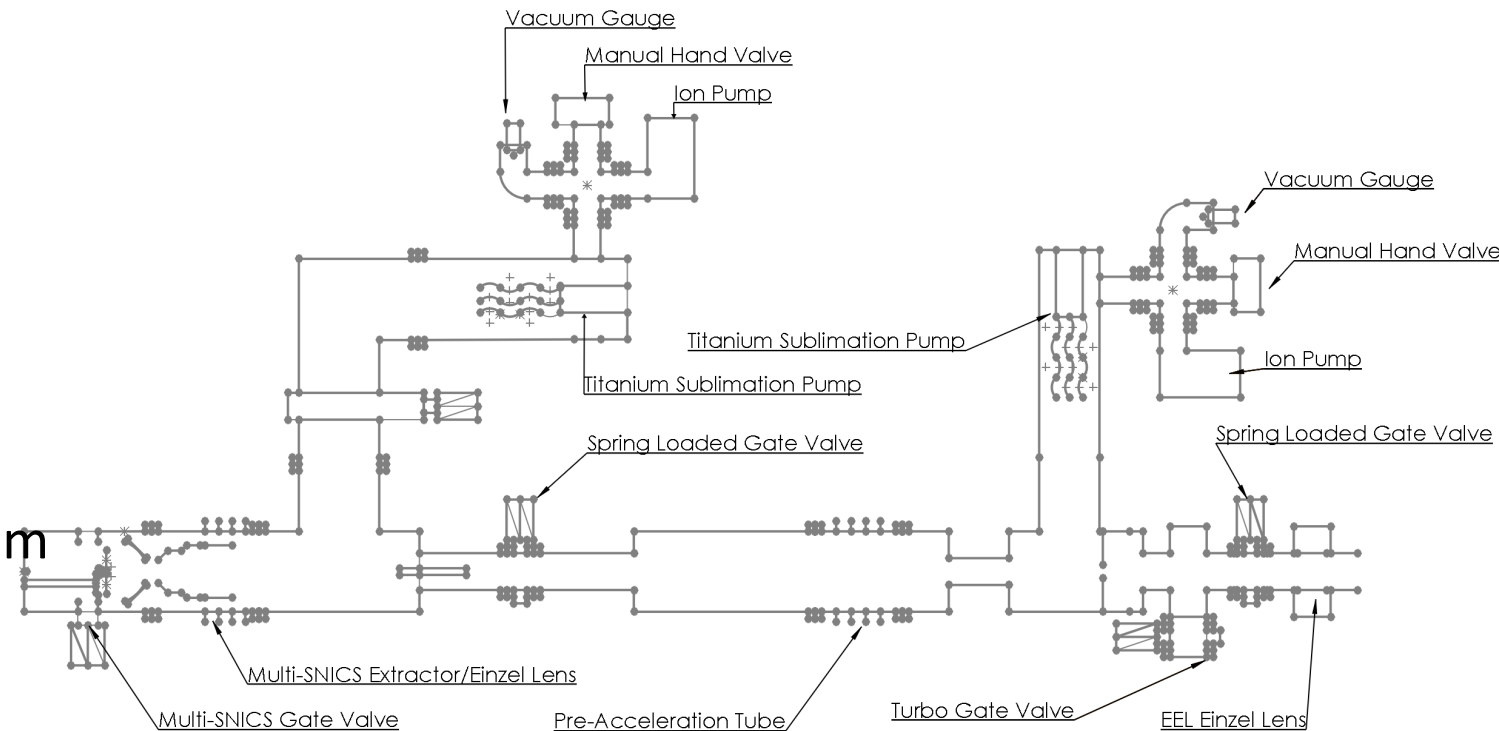

Middleton, Adams and Kollartis, NIM 151 41-46 (1978)

John D. Fox Laboratory at FSU

Florida State University Tritium Source

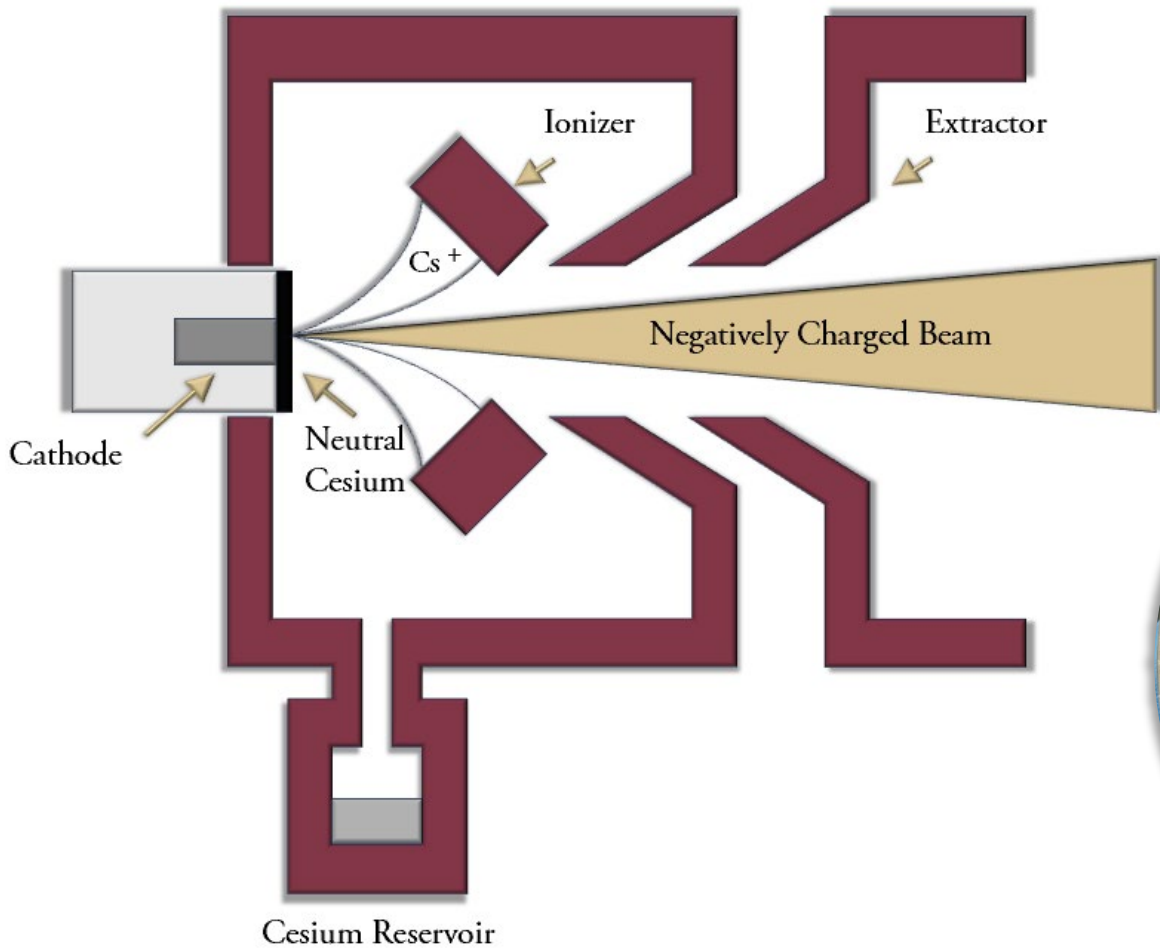

- Multi-cathode SNICS source
- Titanium sublimation pumps
 - 1st on potential
 - 2nd before inflector magnet
- Lower beam current: ~20 nA
- Higher transmission: >98% from source to analyzed beam
- Further **limit** and **negate** any tritium contamination.

Safety Precautions

- **No** handling of gaseous tritium
- Negative Pressure Enclosure (fume hood) around source
- Tritium Monitor (sensitive to $1 \mu\text{C}/\text{m}^3$)
 - Another monitor sensitive to $0.1 \mu\text{C}/\text{m}^3$ will be installed
- Interlock System
- Titanium Sublimation Pumps
- “Unique” equipment for tritium campaigns
 - LE buncher
 - Slits
 - Beam stops

MC-SNICS

Cathodes

- 9.5 mm x 6.5 mm tantalum Jacket
- 6 mm x 2 mm titanium insert
- 5 tritiated cathodes
- 5 deuterated cathodes
- Carbon cathodes
- Up to 20 spots

Pneumatics

Power Supplies

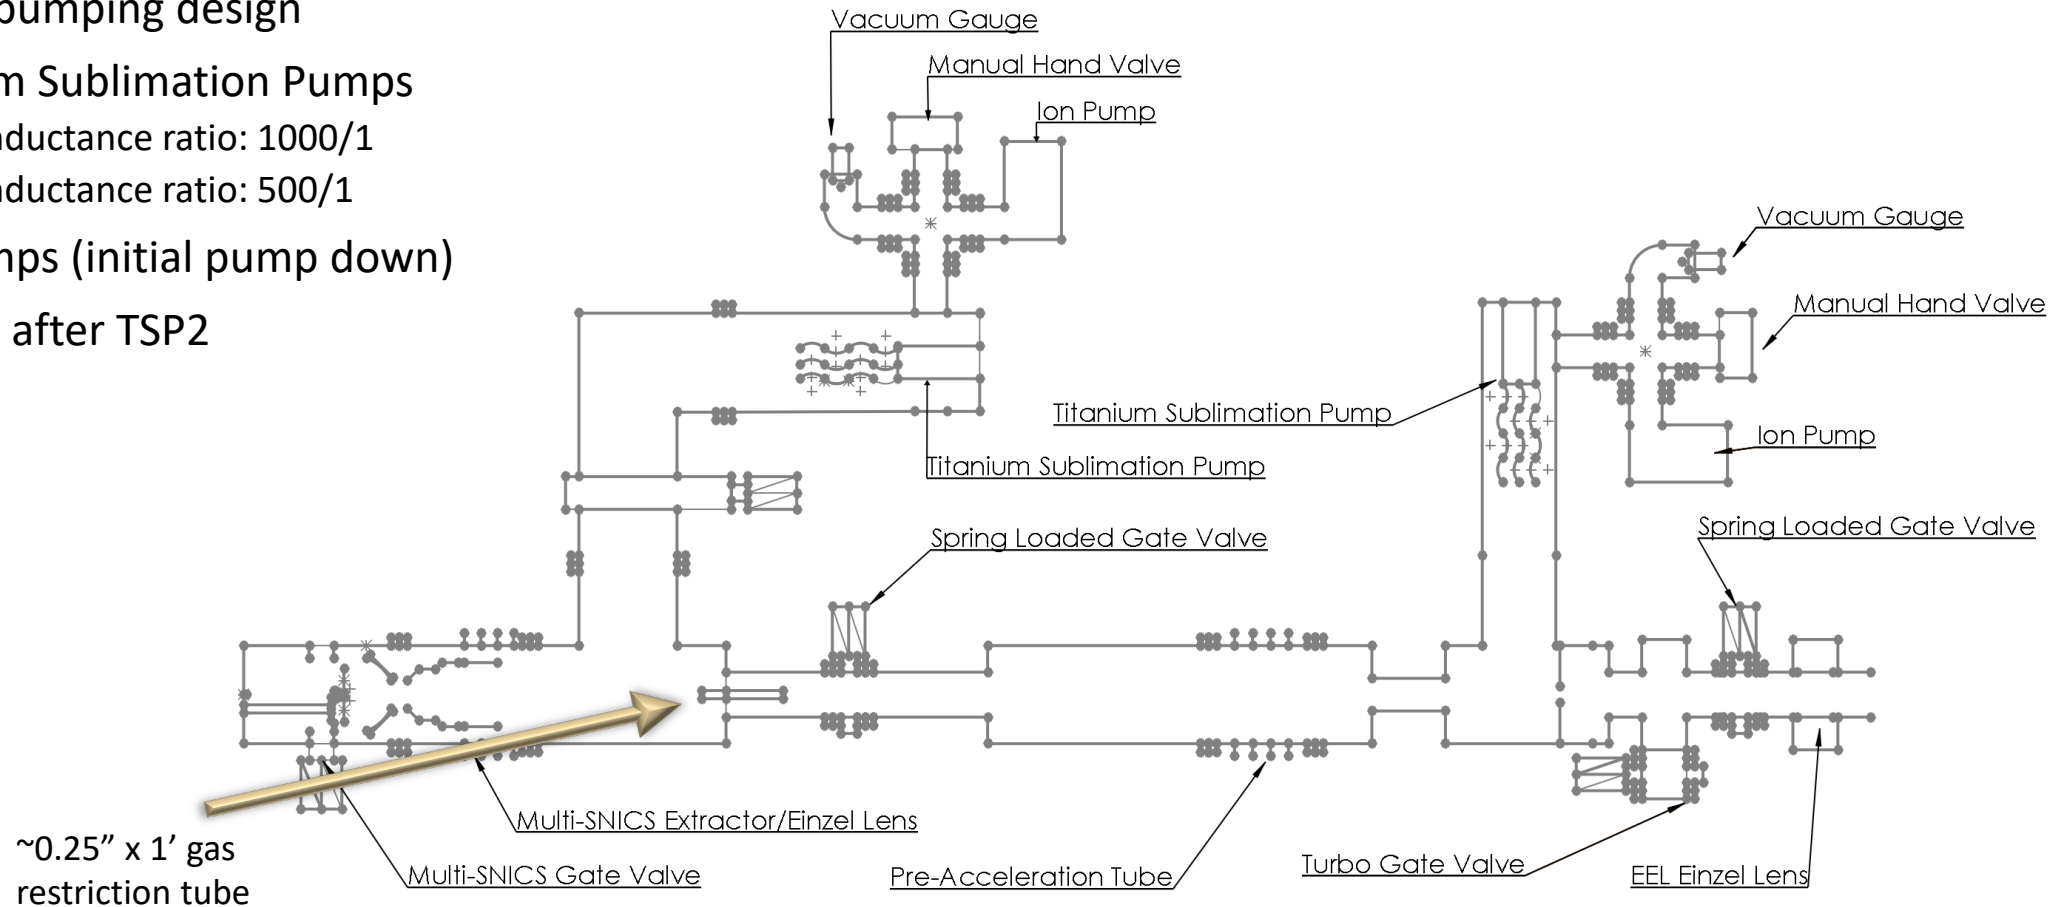

Cooling

Vacuum

- Differential pumping design
- Two Titanium Sublimation Pumps
 - TSP1 conductance ratio: 1000/1
 - TSP2 conductance ratio: 500/1
- Two Ion Pumps (initial pump down)
- Turbo pump after TSP2

Vacuum

- Removeable liner inside of TSP to be declared as radiological waste → Smaller and cheaper removal

~0.25" x 1' gas restriction tube

Fume Hood

- Florida State University and CENTAUR sponsored duct work installed.
- Fume hood designed and built around the source for tritium evacuation
- $\sim 300\text{CFM} \rightarrow \sim 100\text{FPM}$ face velocity around the hood

Fume Hood

- Exhaust from roughing pump is released within fumehood
- Tritium monitor samples all outgoing air
 - Regulatory limit : 0.3 Ci /yr
 - Our goal: 200 μ Ci/yr

Fume Hood

- All tritiated cathodes will be sealed until under the hood
- All cathodes and tritium related devices will always be under the fume hood
- Ports for accessing and working on both sides of the source

Interlock System

Ground

~60kV

~75kV

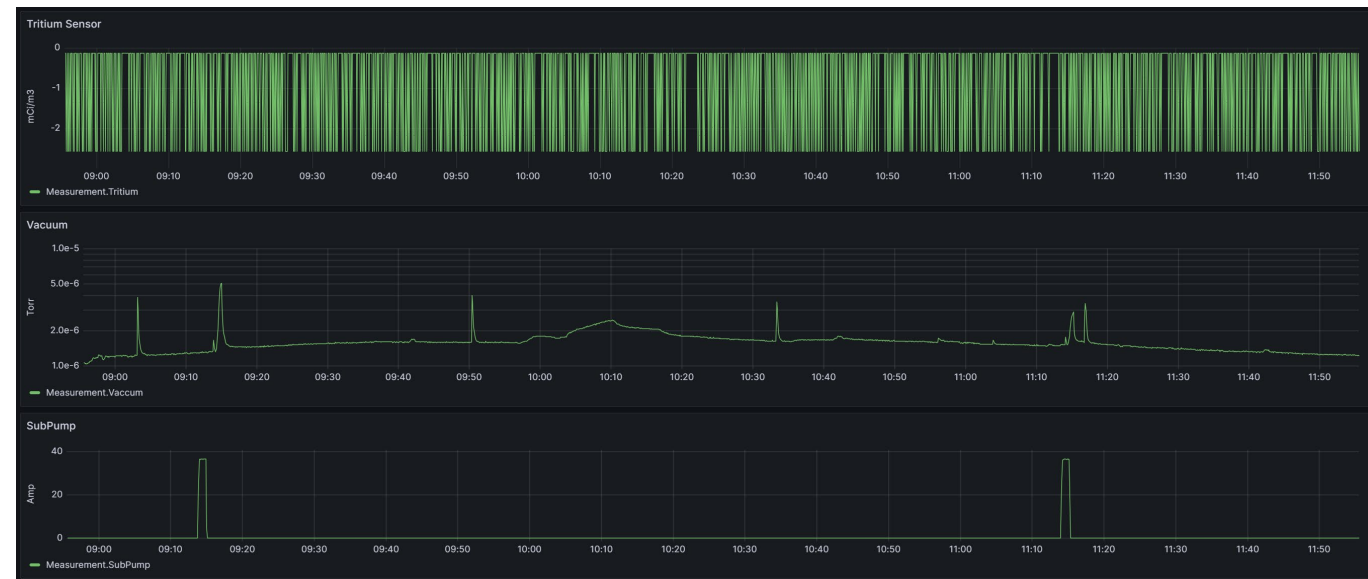

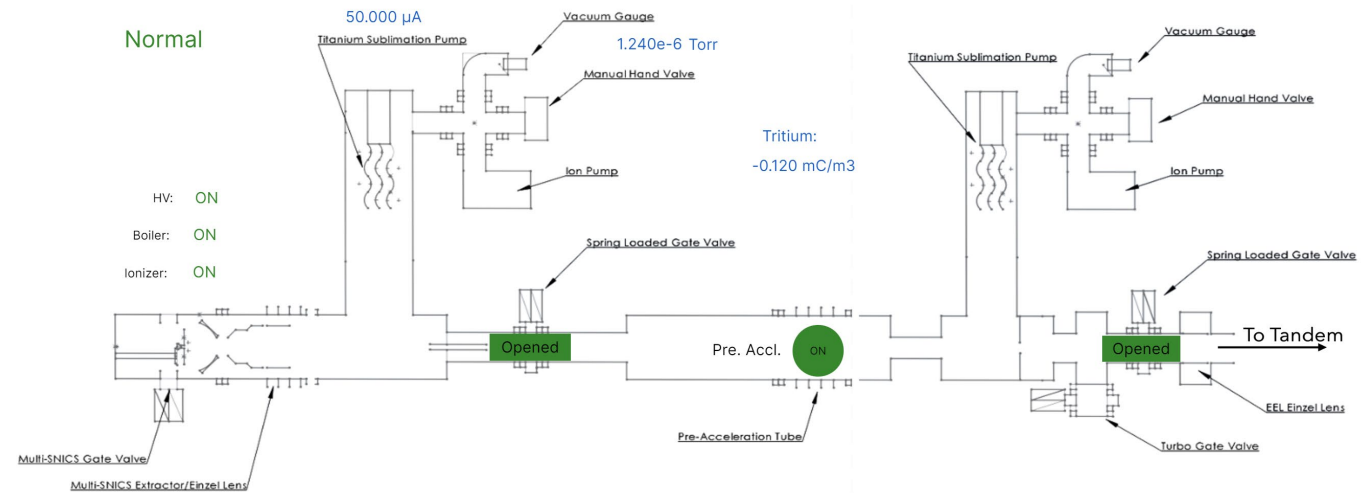

Interlock System

Exception Condition	Interlock Trip		
	Level 1: HV Off	Level 2: Vacuum Isol.	Level 3: Power Off
Cage door opened	X		
Vacuum above threshold	X	X	
Coolant flow supply trip	X	X	
Coolant flow return trip	X	X	
Smoke detector alarm	X	X	X
Fume hood flow trip	X	X	X
Tritium monitor trip	X	X	X
Power failure	X	X	X
Emergency button	X	X	X

Interlock System

- Grafana is used to monitor the interlock in the control room
- Record what caused a source trip and what level of trip occurred
- Record tritium levels, vacuum levels, and TSP1 current

Deuterium Cathode Fabrication

- Titanium absorbs hydrogen → Solid-state hydrogen cathodes
- In house deuterium loading, **outsourced** tritium loading
- ARC approved bottle design for their manifold
- How much hydrogen can we put into these cathodes?

Courtesy of Dr. Janard

Deuterium Cathode Fabrication

- Insert titanium cathode into bottle and fill with ~ 500 Torr of deuterium
- Heat to $>550^{\circ}\text{C}$ and bake for $\sim 1\text{h}$
- Allow to cool back to room temp. measure gas pressure difference (typically ~ 100 Torr)

Deuterium Cathode Testing

- Always around a 1:1 ratio of deuterium to titanium determined by the loss of D as well as weight of cathode
- This method successfully produced a deuteron beam for experiments within the FSU lab.

Initial Beam Extraction

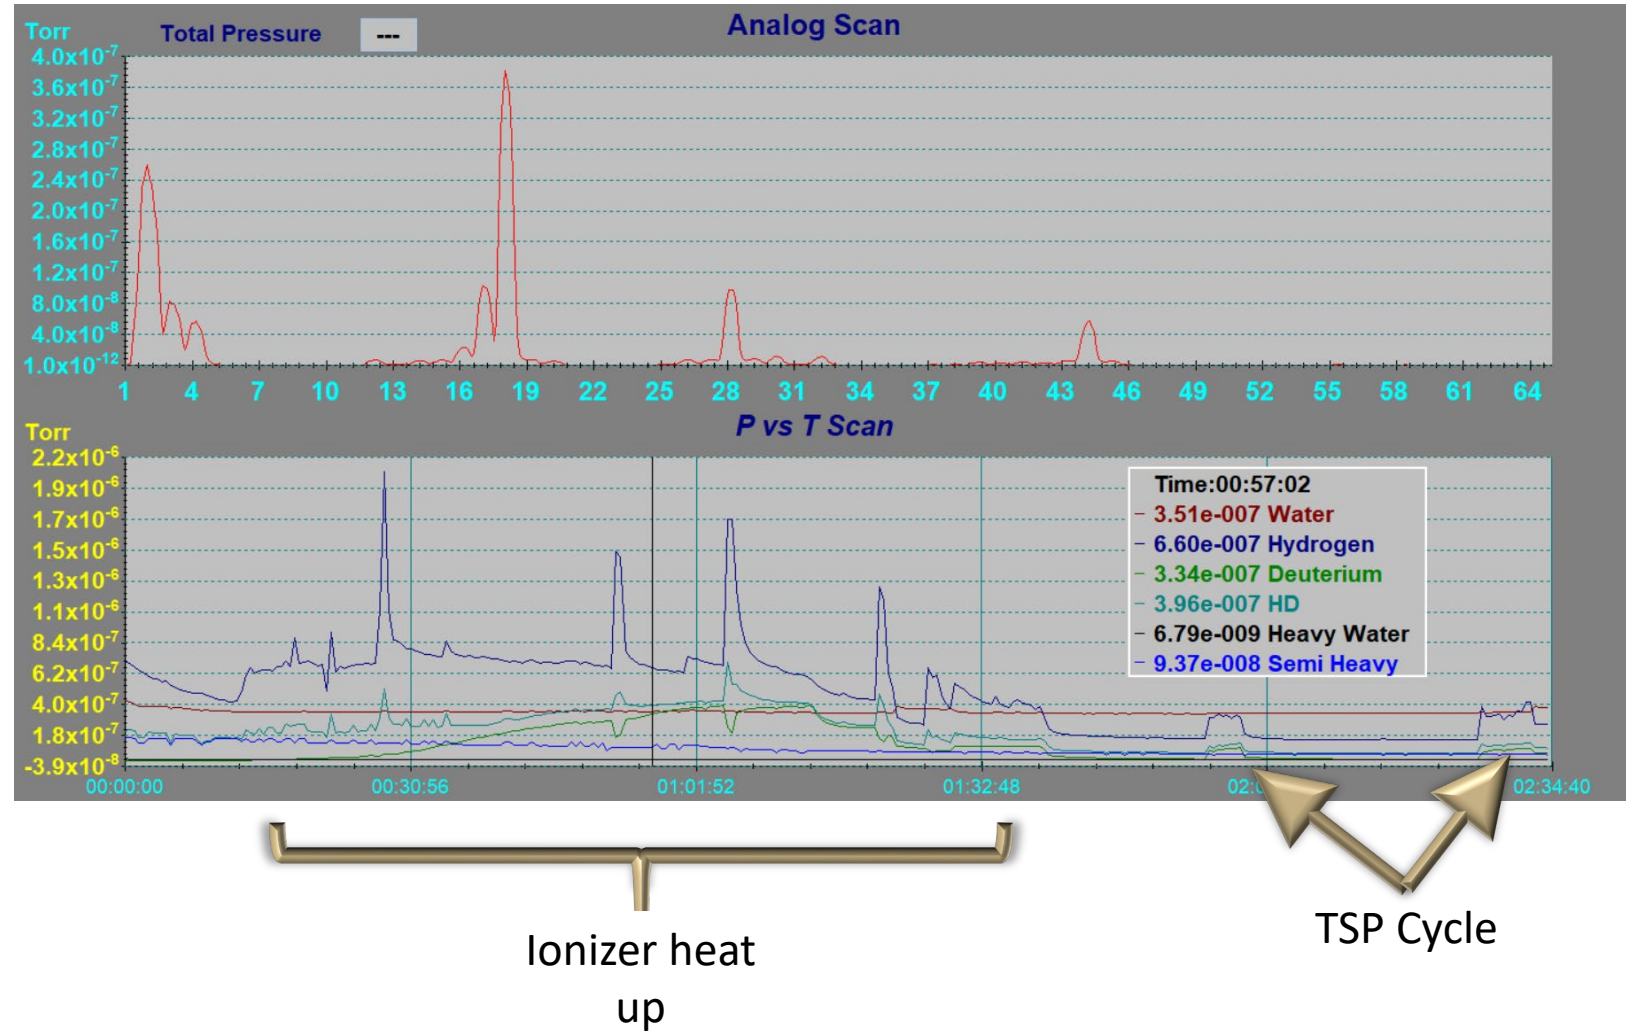

Initial Beam Extraction

- Determine where deuterium goes → will be where tritium goes
- Residual Gas Analyzer to take measurements immediately after injector
- Show that very little deuterium makes it out of the source cavity

Initial Beam Extraction

- 99.9% of deuterium remains in source beamline
- RGA readings show that only on initial ionizer heat up and when TSP1 cycled does deuterium end up beyond the gas restriction
- Still $<1 \times 10^{-6}$ Torr, including HD,D, HDO and D₂O where TSP2 is placed

Initial Beam Extraction

- ~20-40nA used for about 5 days
- This consumed ~10% of a single cathode by mass of titanium
- → 1000 hours of beam time per cathode @ 20nA
- 0.1% of the consumed cathode is ultimately accelerated

Tritium Cathode

- Inside the current geometry of a 2 mm x 6 mm Titanium pellet, about 20 Ci of tritium can be baked in per pellet
- → 100 Ci = 5 Cathodes
- Bottle was shipped to vendor, baked by vendor, backfilled with Argon, then sent back to us

What does this mean for tritium?

- 90% Deuteron Transmission  • 90% Triton Transmission (the rest ends up on disposable slits)
- Only about 0.1% of the sputtered deuterium ends up down the beam line  • 99.9% of the sputtered tritium will be left in the source cavity and TSP1 based on RGA analysis
- We plan on ~20nA of triton intensity  • ~3000h of beam time for a triton campaign (assuming half the tritium is usable)

Campaign

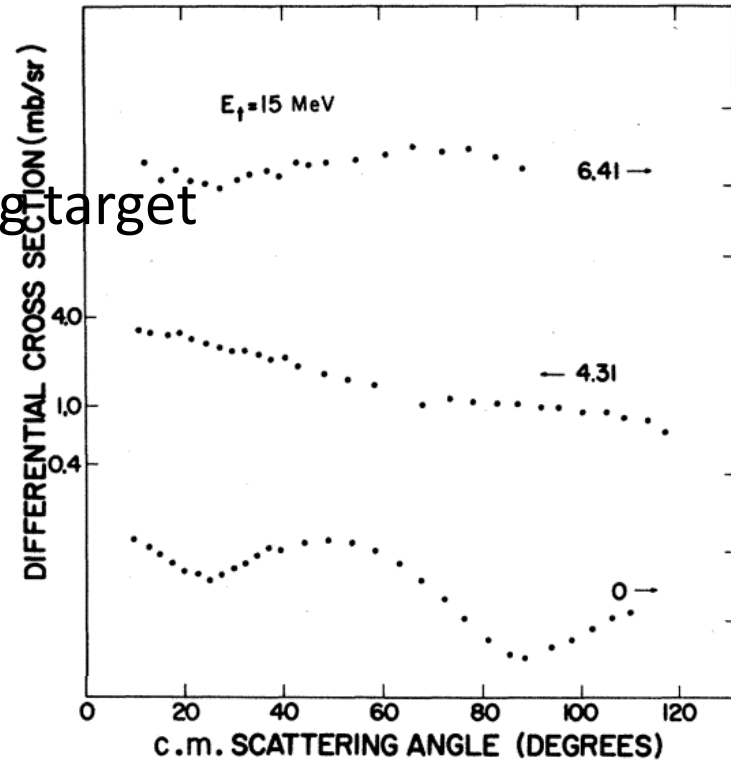

- 3000 hours over two years
- ~20 nA estimated from observed deuterium consumption
- At end of campaign:
 - Remove tritiated cathodes
 - Remove TSP1 liner
 - Remove “unique” equipment
 - Radiation survey

First Experiments

First Experiments

- ${}^7\text{Li}(t,p){}^9\text{Li}$
 - Los Alamos
 - 15 MeV
 - 320 $\mu\text{g}/\text{cm}^2$ self supporting target

P.G. Young and Richard H. Stokes, PRC 1597-1601 (1971)

First Experiments

- ${}^7\text{Li}(t,p){}^9\text{Li}$
 - 15 MeV
 - 200 $\mu\text{g}/\text{cm}^2$ self supporting target
- For 10000 counts
 - $E_{\text{ex.}} = 0 \text{ MeV}$ (B = 6 kG) ~ 1.3 hours
 - $E_{\text{ex.}} = 4.30 \text{ MeV}$ (B = 5 kG) ~ 1.1 hours
 - $E_{\text{ex.}} = 6.40 \text{ MeV}$ (B = 3.5 kG) ~ 10 hours

First Experiments

- $^{12}\text{C}(t,p)^{14}\text{C}$
 - Upenn
 - 18 MeV
 - $50 \mu\text{g}/\text{cm}^2$ self supporting target

S. Mordechai, et al., NPA 301 463-476 (1978)

First Experiments

- $^{12}\text{C}(t,p)^{14}\text{C}$
 - 15 MeV
 - 50 $\mu\text{g}/\text{cm}^2$ self supporting target
- For 10000 counts
 - $E_{\text{ex.}} = 6.09 \text{ MeV}$ ($B = 6 \text{ kG}$) ~ 14.1 hours
 - $E_{\text{ex.}} = 6.59 \text{ MeV}$ ($B = 6 \text{ kG}$) ~ 35 hours
 - $E_{\text{ex.}} = 6.73 \text{ MeV}$ ($B = 6 \text{ kG}$) ~ 3.4 hours
 - $E_{\text{ex.}} = 7.01 \text{ MeV}$ ($B = 6 \text{ kG}$) ~ 3.2 hours

Summary

- A dedicated MC-SNICS has been installed at John D. Fox Laboratory
 - Complete with Infrastructure, vacuum, fume hood, interlocks
- Deuterium has been successfully implanted into a solid-state cathode
 - Tritium implantation was handled similarly but by an **outside vendor**
- Can easily produce expected $\sim 20\text{nA}$ of beam for 3000h
 - Based on material loss in cathodes after deuteron beam testing
- Next: use a **single** tritium cathode to **safely** commission the source
